Fecha:

3 de Junio 2026

Repository URL:

<https://github.com/salva1984/ci-promote-g2>

Features:

1. Register a member, with a name and a unique identifier. - Assigned to Nahim Diaz
2. Loan a book to a member. A book that is already on loan cannot be loaned again. - Assigned to Shirley Aragon
3. Return a book, marking it available again. - Assigned to Gabriel Tumbaco
4. List the books a member currently has on loan. - Assigned to Salvador Muñoz
5. Report the loans that are overdue, given a due date for each loan. - Assigned to Anthony Navarrete

You can find the workflow file in this URL:

<https://github.com/salva1984/ci-promote-g2/blob/main/.github/workflows/ci.yml>

Action tab screenshot (w/passing test)

The screenshot displays the GitHub Actions interface for the repository 'salva1984 / ci-promote-g2'. The 'Actions' tab is selected, showing a workflow run for 'ci.yml' triggered by a pull request. The run is successful, with a status of 'Success' and a total duration of 13s. The workflow consists of two jobs: 'test' and 'release', both of which passed. The 'test' job is highlighted with a green checkmark. The 'Annotations' section shows a warning about deprecated Node.js 20 actions.

Required approvals

1 ▾

The number of approving reviews that are required before a pull request can be merged.

☐ **Dismiss stale pull request approvals when new commits are pushed**
New, reviewable commits pushed will dismiss previous pull request review approvals.

☐ **Require review from specific teams**
A collection of reviewers and associated file patterns. Each reviewer has a list of file patterns which determine the files that reviewer is required to review.

☐ **Require review from Code Owners**
Require an approving review in pull requests that modify files that have a designated code owner.

☐ **Require approval of the most recent reviewable push**
Whether the most recent reviewable push must be approved by someone other than the person who pushed it.

☐ **Require conversation resolution before merging**
All conversations on code must be resolved before a pull request can be merged.

Allowed merge methods

Merge, Squash, Rebase ▾

When merging pull requests, you can allow any combination of merge commits, squashing, or rebasing. At least one option must be enabled.

19 To https://github.com/salva1984/ci-promote-g2
20 * [new tag]          v1.0.47 -> v1.0.47
```

Continuous Integration decision:

1. To switch from CI to CD, branch protection rules must be updated to allow automated auto-merging instead of requiring manual peer reviews. Additionally, a deployment step must be added to the pipeline to automatically publish or distribute the compiled application as soon as the tests pass.
2. The most dangerous feature to automate is "Loan a book" because it handles critical validation limits. Since the application relies on a single shared JSON file to persist data, an undetected bug could easily corrupt or overwrite the file, causing permanent data loss and disrupting library operations.
3. To mitigate the inherent dangers of Continuous Deployment, advanced engineering teams implement automated rollbacks as a crucial safety net before trusting automatic releases. This mechanism links the deployment pipeline with real-time monitoring tools (such as Prometheus or Grafana) that track strict system health thresholds, such as a command error rate exceeding 5% or unhandled database exceptions. If a newly deployed automated release breaches these thresholds during its initial minutes in production, the monitoring system autonomously triggers an alert that executes a roll-back script in the pipeline

Cited from :

<https://ctox.com/best-practices-for-rollback-plan-in-secure-deployments/>

4. As a development team, we have decided not to enable Continuous Deployment for CaféLibro at this time. The application is in an early development phase structured around a short-duration workshop, meaning our current automated pytest suite is basic and lacks the coverage required to catch complex concurrency flaws or structural JSON corruption. Handing off direct-to-production deployment relying solely on minimal unit tests would be highly irresponsible for the library's business stability. For us to reconsider this stance in the future, several technical milestones must be achieved: elevating code coverage above 95% with robust integration tests for JSON persistence, establishing an automated staging environment to simulate real terminal CLI usage, and deploying an automated backup system to clone the JSON state before any live software update.

Questions

1. Why is continuous integration worth the setup effort on a team project? What goes wrong on a shared repository without it?

Setting up CI ensures that code conflicts and system failures are detected immediately after they are introduced. Because developers integrate in small increments, pinpointing the exact cause of a broken test is straightforward, which keeps the cost and time to fix it low while maintaining a main branch that is always correct and passing. Without CI, developers could work in isolation for extended periods and integrate their changes late. This results in a lot of merge conflicts, the resulting bugs are incredibly difficult to locate and resolve.

2. This workshop used GitHub Actions. Research at least two other tools that do continuous integration and delivery (for example Jenkins, GitLab CI, CircleCI, Travis CI, or others). For each, say briefly how a project configures it and where it runs the build.

Jenkins:

Configuration: Set up using a domain-specific language (Groovy syntax) inside a text file named a Jenkinsfile, or configured manually via its web interface.

Build Environment: Runs the build on dedicated integration servers, cloud virtual machines, or self-hosted local infrastructure managed entirely by the user.

GitLab CI:

Configuration: Configured using a structured .gitlab-ci.yml file placed directly in the root directory of the repository.

Build Environment: Executes builds on "GitLab Runners", which can be hosted in GitLab's cloud ecosystem or installed on a team's own private server hardware.

3. Of the tools you compared, including GitHub Actions, which would you choose for the course project, and why? Consider where your code lives, the cost, and how much setup each one needs.

We choose GitHub Actions for the following reasons:

- **Code Location:** The team's public repository is already hosted natively on GitHub, completely eliminating the need to sync external platforms or handle third-party webhooks.
- **Cost:** It is entirely free of charge for public open-source repositories, removing any financial barriers for a student budget.
- **Setup Effort:** The setup overhead is virtually zero. There are no servers to maintain or software packages to install; configuration requires nothing more than adding a ci.yml file under the .github/workflows/ directory.

4. How does continuous integration fit with the way agile teams work in short iterations?

Agile teams operate in rapid, short iterations designed to deliver functional software continuously. Continuous Integration acts as the technical backbone for this rhythm by allowing developers to safely merge small increments of code frequently. Automated testing on a dedicated server acts as an immediate safety net, ensuring that fast-paced changes do not cause regressions or break existing features. This keeps the codebase perpetually stable and deployable at the end of every sprint cycle.

Conclusions

- Automating tests with pytest in GitHub Actions within the ci-promote-g2 repository ensured the early detection of bugs before each integration. This, combined with branch protection rules requiring peer reviews and mandatory passing checks, effectively shielded the stability of the main branch.
- The pipeline practically demonstrated its value as a quality guardrail when an intentional breaking commit in the menu component triggered a test failure and successfully blocked the merge. Once the assertion error was corrected, the pipeline seamlessly flipped to green and unblocked the integration , proving that automated guardrails effectively isolate defects on developer branches before they can degrade the mainline's integrity.

Recommendations

- It is highly recommended to replace the flat JSON file with a relational database to handle concurrency safely and eliminate data corruption risks.

Additionally, the unit and integration test suites must expand to exceed 95% code coverage before the team considers any future transition to CD

- Setting up an automated staging environment to accurately simulate the terminal CLI's real-world behavior is highly advisable. Furthermore, an automated backup system should be integrated to clone the data state immediately prior to any software deployment in production.
